

**MATHEMATICS ENRICHMENT CLUB.**  
**Solution Sheet 6, June 18, 2018**

1. Firstly, we note that  $2x + 5y \neq 0$ . Then

$$\frac{x + 3y}{2x + 5y} = \frac{4}{7}$$

$$7(x + 3y) = 4(2x + 5y)$$

$$7x + 21y = 8x + 20y$$

$$x = y$$

The solution is then  $x = y \neq 0$ .

2. The four digit numbers that satisfy the first equation are 1064, 1164, 1264 and so on. Of these, only 1764, 3364, 8464 are square. These satisfy the first equation for  $n = 17$ , 33 and 84 respectively. Then  $201 \times 84 + 64 = 16948$  which is larger than 4 digits, and  $201 \times 33 + 64 = 6697$  which isn't square. So  $n = 17$ .
3. The solution looks like this:

4. (a) Consider the integers in mod 4. Then it is clear that the only squares in mod 4 are 0 and 1.
- (b) Let the three integers be  $x$ ,  $y$  and  $z$  and consider them in mod 4. An odd integer is congruent to either 1 or 3 mod 4. So if all three integers are odd, we can draw up the following table where all calculations have been carried out in mod 4:

$x$	$y$	$z$	$x + y$	$x + z$	$y + z$
1	1	1	2	2	2
1	1	3	2	0	0
1	3	3	0	0	2
3	3	3	2	2	2

We know from part (a) that squares are either 0 or 1 mod 4, so none of these combinations works.

Without loss of generality, suppose that  $x$  is even but both  $y$  and  $z$  are odd. Then the table is as follows:

$x$	$y$	$z$	$x + y$	$x + z$	$y + z$
0	1	1	1	1	2
0	1	3	1	3	0
0	3	3	3	3	2
2	1	1	3	3	2
2	1	3	3	1	0
2	3	3	1	1	2

Once again, we see that this does not work if two of the integers are odd. Consequently, at most one of the integers is odd. (It can be seen that  $x, y \equiv 0$  and  $z \equiv 1$  or  $x, y \equiv 2$  and  $z \equiv 3 \pmod{4}$ , for instance, might work.)

(c) Try 19, 30 and 6.

5. Let  $KG$ ,  $LG$  and  $GM$  be perpendiculars from  $G$  to  $AB$ ,  $AC$  and  $BC$ , respectively. Then  $\triangle BKG$  and  $\triangle BGM$  are two right triangles with a smaller angle and a hypotenuse in common, so  $\triangle BKG \cong \triangle BGM$ . Thus  $GK = GM$ . By a similar argument, it can be shown that  $GM = GL$ . Consequently,  $\triangle GAK \cong \triangle GAL$ , and so  $GA$  bisects  $\angle BAC$ , as required.

As you can see from the proof, the points  $K$ ,  $L$ , and  $M$  are equidistant from  $G$ . Thus  $G$  is the centre of a circle that can be drawn inside the triangle and tangent to each side, which is called the inscribed circle.

### Senior Questions

1. Use mathematical induction.

2. Recall that  $1^2 + 2^2 + 3^2 + \dots + n^2 = \frac{n(2n+1)(n+1)}{6}$ . Then  $\lim_{n \rightarrow \infty} \frac{1^2 + 2^2 + 3^2 + \dots + n^2}{n^3} = \frac{1}{3}$ .

3. (a) The graph should be as follows:

(b) And the graph with the inverse function shown is as follows:

(c) Let  $y = W(x)$ . Then by definition,  $x = ye^y$ . Differentiating implicitly with respect to  $x$ , we have

$$1 = \frac{dy}{dx}e^y + ye^y \frac{dy}{dx}$$

$$1 = e^y(1 + y) \frac{dy}{dx}$$

But  $e^y = \frac{x}{y}$ , and so

$$1 = \frac{x(1+y)}{y} \cdot \frac{dy}{dx}$$
$$\frac{dy}{dx} = \frac{y}{x(1+y)}$$

And since  $y = W(x)$ , the result follows.
